==========

MASTER AI AGENT PROMPT — PHASE 2

JIT Branch Predictor: Python Slowness vs JIT Optimization

Make the core idea VISIBLY MEASURABLE in output

==========

AGENT MISSION

You are continuing the JIT Branch Predictor COA project.
The existing project simulates a 5-stage pipeline with 4 predictors.

YOUR JOB in this phase:

- Analyse the current project files for completeness
- Add a "Python-naive" simulation mode vs "JIT-optimized" simulation mode
- Generate clear, readable terminal output showing the speedup
- Generate a visual comparison chart (PNG)
- Make the core idea — JIT optimization reduces pipeline stalls and increases IPC — UNMISTAKABLY visible in every output format

The result should be: anyone who runs this project sees immediately
that Python-style branch patterns hurt performance, and JIT-aware
prediction fixes it with measurable numbers.

SECTION A — ANALYSE EXISTING PROJECT FIRST

Before writing any new code, do the following checks.
Report what exists and what is missing.

Check 1: File completeness

Verify these files exist and are non-empty:

```
top.v
pipeline/if_stage.v
pipeline/if_id_reg.v
pipeline/id_stage.v
pipeline/id_ex_reg.v
pipeline/ex_stage.v
pipeline/ex_mem_reg.v
pipeline/mem_wb_stage.v
pipeline/register_file.v
pipeline/alu.v
pipeline/hazard_unit.v
pipeline/forwarding_unit.v
pipeline/flush_control.v
predictors/predictor_if.v
predictors/pred_static.v
predictors/pred_1bit.v
predictors/pred_2bit.v
predictors/pred_ghr.v
memory/instr_mem.v
memory/data_mem.v
tb/tb_top.v
tb/traces/loop_heavy.mem
tb/traces/dispatch_heavy.mem
tb/traces/mixed.mem
analyze.py
```

Check 2: Compilation test

Run this command and report any errors:

```bash
iverilog -o test_compile \
  tb/tb_top.v top.v \
  pipeline/if_stage.v pipeline/if_id_reg.v \
  pipeline/id_stage.v pipeline/id_ex_reg.v \
  pipeline/ex_stage.v pipeline/ex_mem_reg.v \
  pipeline/mem_wb_stage.v pipeline/register_file.v \
  pipeline/alu.v pipeline/hazard_unit.v \
  pipeline/forwarding_unit.v pipeline/flush_control.v \
  predictors/predictor_if.v predictors/pred_static.v \
  predictors/pred_1bit.v predictors/pred_2bit.v \
  predictors/pred_ghr.v \
  memory/instr_mem.v memory/data_mem.v 2>&1
```

Check 3: Fix any errors found

If compilation fails:

- Read the error message carefully
- Identify which file has the issue

- Fix the port mismatch, missing wire, or syntax error
- Re-run compilation until it passes with zero errors

SECTION B — CORE CONCEPT: TWO WORLDS TO COMPARE

The project must simulate and compare TWO clearly distinct scenarios:

World 1 — "Python Unoptimized" (naive execution)

This represents Python/Java bytecode running on a CPU with a STATIC
predictor — no intelligence, always predicts not-taken.
Branch-heavy JIT code hits mispredictions constantly.
This is the SLOW world.

Characteristics:

- Predictor: Static (always not-taken)
- Trace: dispatch_heavy.mem (alternating taken/not-taken — worst case)
- High misprediction rate (~55-60%)
- Many stall cycles injected
- Low effective IPC (~0.45-0.55)

World 2 — "JIT Optimized" (our hardware solution)

This represents Python/Java bytecode running on a CPU with a GLOBAL
HISTORY REGISTER predictor — learns branch patterns over time.
This is the FAST world our hardware design creates.

Characteristics:

- Predictor: GHR (global history register)
- Trace: dispatch_heavy.mem (same code — only predictor changes)
- Low misprediction rate (~15-20%)
- Very few stall cycles
- High effective IPC (~0.82-0.89)

The KEY INSIGHT: same Python program, same CPU hardware, same instructions
— ONLY the branch predictor hardware changes. The speedup is PURELY from
better prediction hardware. That is the COA contribution.

SECTION C — NEW FILES TO CREATE

NEW FILE 1: tb/traces/python_naive.mem

```
# Python-naive trace: simulates Python interpreter dispatch loop
# High-density alternating branches — type checks, isinstance, dispatch
# Pattern: branch, NOP, branch, NOP — predictor has no pattern to learn
# This is the "slow Python" workload
```

SECTION D — UPDATED top.v WITH PERFORMANCE COUNTER FIX

The existing top.v may have a stall counter bug where both stall AND flush are counted separately, inflating the stall number. Replace the performance counter block in top.v with this corrected version.

Find this block in top.v:

```verilog
    // ── Performance Counters ──────────────────────────────────────────
    always @(posedge clk or posedge rst) begin
```

Replace the ENTIRE always block (from always to end) with:

```verilog
```

```
    // ── Performance Counters ──────────────────────────────────────
    // stall_cycles counts cycles where no useful instruction completes
    // This includes: load-use stalls AND misprediction flush cycles
    always @(posedge clk or posedge rst) begin
        if (rst) begin
            total_cycles         <= 32'd0;
            total_branches       <= 32'd0;
            total_mispredictions <= 32'd0;
            total_stalls         <= 32'd0;
        end else begin
            total_cycles <= total_cycles + 32'd1;

            // Count branches when they are in the EX stage
            if (ex_is_branch)
                total_branches <= total_branches + 32'd1;

            // Count mispredictions
            if (mispredicted)
                total_mispredictions <= total_mispredictions + 32'd1;

            // Count wasted cycles:
            //   flush = 2 wasted cycles per misprediction (counted when flush fires
            //   stall = 1 wasted cycle per load-use hazard
            // Use priority: flush takes precedence
            if (flush)
                total_stalls <= total_stalls + 32'd2; // 2-cycle penalty
            else if (stall)
                total_stalls <= total_stalls + 32'd1; // 1-cycle penalty
        end
    end
```

SECTION E — BUILD AND RUN: FULL SEQUENCE

Run these commands in order from the project root directory.

Step 1: Create new trace files

```bash
# The agent should have created these already in Section C
# Verify:
ls tb/traces/
# Should show: dispatch_heavy.mem  jit_optimized.mem
#              loop_heavy.mem  mixed.mem  python_naive.mem
```

Step 2: Compile showcase testbench

```bash
```

```
iverilog -o showcase_sim \
  tb/tb_showcase.v \
  top.v \
  pipeline/if_stage.v \
  pipeline/if_id_reg.v \
  pipeline/id_stage.v \
  pipeline/id_ex_reg.v \
  pipeline/ex_stage.v \
  pipeline/ex_mem_reg.v \
  pipeline/mem_wb_stage.v \
  pipeline/register_file.v \
  pipeline/alu.v \
  pipeline/hazard_unit.v \
  pipeline/forwarding_unit.v \
  pipeline/flush_control.v \
  predictors/predictor_if.v \
  predictors/pred_static.v \
  predictors/pred_1bit.v \
  predictors/pred_2bit.v \
  predictors/pred_ghr.v \
  memory/instr_mem.v \
  memory/data_mem.v
```

Step 3: Run showcase simulation

```bash
./showcase_sim | tee simulation_output.txt
```

Expected terminal output (what you should see):

```

╚═══════════════════════════════════════════════════════════════╝

+----------------+----------+----------+----------+----------+
|    METRIC      |  STATIC  |  1-BIT   |  2-BIT   |   GHR    |
|                | (Python) |          |          | (JIT OPT)|
+----------------+----------+----------+----------+----------+
| Branches       |       64 |       64 |       64 |       64 |
| Mispredictions |       37 |       24 |       19 |       11 |
| Miss rate %    |      57% |      37% |      29% |      17% |
```

```
| Stall cycles    |        74 |        48 |        38 |        22 |
| IPC (x100)      |        51 |        66 |        73 |        84 |
+-----------------+-----------+-----------+-----------+-----------+

>> PYTHON (static predictor) IPC  : 0.51
>> JIT OPTIMIZED (GHR) IPC        : 0.84
>> SPEEDUP (JIT vs Python)         : 1.64x faster
>> STALLS ELIMINATED               : 52 cycles
>> MISPREDICTIONS ELIMINATED       : 26

[!!] SIGNIFICANT SPEEDUP ACHIEVED — JIT optimization works.
```

Step 4: Generate charts

```bash
python3 analyze_showcase.py
```

This generates: jit_showcase_results.png

Step 5: View waveform

```bash
gtkwave showcase.vcd &
```

In GTKWave: drag these signals into view window:
clk, rst, if_pc, ex_is_branch, mispredicted, flush, stall
Zoom in on the flush events — you will see exactly 2 NOP cycles appear in the pipeline after each misprediction.

SECTION F — WHAT TO HIGHLIGHT IN YOUR PRESENTATION

Slide 1 — The Problem

Quote this from your simulation_output.txt:
"Python trace: Static predictor → 57% miss rate → IPC 0.51"

Slide 2 — Our Hardware Solution

Quote this:
"Same trace: GHR predictor → 17% miss rate → IPC 0.84"
"That is 1.64x faster — from ONE hardware change."

Slide 3 — The Chart

Show jit_showcase_results.png — the bottom panel (row 3) is the most impactful: red bars (Python) vs purple bars (JIT) with speedup annotations.

Slide 4 — The Waveform

Show showcase.vcd in GTKWave:

- Point to the red flush pulses
- Each one = a misprediction = 2 wasted cycles
- Count them: Static has many, GHR has few
- That visual IS the proof

What to say

"Python code has alternating taken/not-taken branches from type-checking and method dispatch. Static predictors are blind to this. Our GHR predictor learns the correlation — branch A being taken means branch B is not-taken — and predicts correctly. The result is 60% fewer mispredictions and 1.6x better IPC, measured directly in hardware simulation."

SECTION G — AGENT CHECKLIST

Before declaring the project complete, verify ALL of the following:

[ ] All 22 original files exist and compile cleanly
[ ] tb/traces/python_naive.mem created (64 lines)
[ ] tb/traces/jit_optimized.mem created (64 lines)
[ ] tb/tb_showcase.v created with 4 DUT instances
[ ] analyze_showcase.py created
[ ] top.v performance counter block updated
[ ] iverilog compiles showcase_sim with zero errors
[ ] ./showcase_sim runs and prints the full results table
[ ] simulation_output.txt is non-empty
[ ] python3 analyze_showcase.py generates jit_showcase_results.png
[ ] showcase.vcd opens in GTKWave and shows flush events
[ ] Speedup shown for python_naive trace is >= 1.4x
[ ] Chart shows clear red (slow) vs purple (fast) bars

If any check fails — fix it before proceeding.
The project is only complete when ALL boxes are checked.

END OF PHASE 2 AGENT PROMPT
New files added: 4
Files modified: 1 (top.v performance counter)
Primary output: jit_showcase_results.png + simulation_output.txt
Core visible result: 1.5-2.0x IPC speedup with labelled chart
